Submitted: 9 July 2017 / Revised: 5 October 2017 / Accepted: 7 November 2017

#### Abstract

A quantitative Structure-Activity Relationship (QSAR) model was applied to the prediction of the activity of iminochromene derivatives. The inhibition activity of 34 carbonyl reductase 1 (CBR1) inhibitors were modeled with the descriptors of quantum-chemical calculations with density functional theory (DFT) method at B3LYP/6-31G level. This study was conducted using the multiple linear regressions (MLR), the partial least square analysis (PLS) and the principal component analysis (PCA) method. Results displayed that the MLR method predicted of activity good enough. The best model, with seven descriptors was selected. Also it indicates very good consistency towards data variations for the validation methods. The predicted values of activities are in suitable agreement with the experimental results. The obtained results suggested that the PCA method could be more helpful to predict the biological activity of iminochromene derivatives. It is anticipated to be useful to predict the activity of other compounds in the same groups.

KEYWORDS: Quantitative Structure-Activity; Relationship (QSAR); Iminochromene derivatives; Multiple Linear Regression (MLR); Partial Least Square (PLS); Density Functional Theory (DFT); Principal Component Analysis (PCA).

## 1. INTRODUCTION

A branch of the short-chain dehydrogenase/reductase group is human carbonyl reductase 1 (CBR1) that decrease a variety of carbonyl compounds including therapeutic drugs [1]. CBR1 inhibitors are purposed to be suitable agents for adjutant therapy with twofold useful effect in prolongation the anticancer effect of the anthracyclines while reducing cardiotoxicity[2]. As well as, CBR1 decreases a wide variety of xenobiotic carbonyl alcohols, which are easier to be conjugated and omitted. Also, selective inhibitors of CBR1 may be helpful in clarifying the physiological functions of the enzyme and its portion to metabolism of lately developed carbonyl-containing drugs [3]. CBR1 is prevented by structurally various compounds, which are divided into natural and synthetic inhibitors. Some of synthetic inhibitors are 3-(1-tert-butyl-4-amino-1Hpyrazolo [3,4-d]pyrimidin-3-yl)phenol (hydroxy-PP), triclosan, ethacrynic acid, indomethacin and zearalenone analogues [4-6]. The natural inhibitors are resveratrol [7] and flavonoids [8-9] that a molecular docking study of four flavonoids in CBR1 proposed their different relative positions in its active site [10]. Using the chosen CBR1 inhibitor as the rector compound, 8-hydroxy-2-iminochromene ( $1 \mathrm{a}-1 \mathrm{q}$ ) and 8hydroxycoumarin (2a-2q) derivatives by displacing the pyridine moiety bound to the carboxamide of the chromene ring with substituted phenyl or benzyl rings have been synthesized by Hu and coworkers ${ }^{11}$. These compounds are novel and potent inhibitors that are selective to human CBR1. The structures of the compounds and their inhibitory activities for CBR1 are summarized in table 1 [11].

The QSAR methods are mathematical equations describing chemical structure to their target property (biological activity). These predictive models remit information that is effective for medicinal chemistry and drug discovery [12-14]. QSAR study on heterocyclic and aromatic sulfonamides compounds including 8-quinoline-sulfonyl carbonic anhydrase (CA) inhibitors with topical activity as antiglaucoma agents has been performed topologically with first-order valence connectivity index [15]. The 3D QSAR pharmacophore models for aldo-keto reductase family 1 B10 were generated using Density functional theory calculations [16]. The 2D, 3D QSAR and molecular docking studies on receptor antagonising thiazolo[3,2-a]pyrimidines as antipsychotic agents have been performed using VLife MDS3.5 software [17] .

Molecular docking, Comparative Molecular Field Analysis (CoMFA) and Comparative Molecular Similarity Indices Analysis (CoMSIA) studies were investigated on a set of 4-azasteroidal human steroid 5areductase inhibitors [18]. QSAR and docking of 1, 4-Dihydropyridines as novel antitubercular agents has been studied [19]. Classical QSAR studies on chromene derivatives as lanosterol demethylase inhibitor have been performed by Vasanthanathan et al. [20]. Also, cytotoxic activity assessment and QSAR study of chromenebased chalcones have been investigated [21].

In the present study, QSAR analysis was investigated for on 8-hydroxy-2-iminochromene derivatives to organized quantitative relationship between biological activity of derivatives and their structural and physicochemical properties. Therefore; we suggest linear models by using chemometrics tools such as PCA, MLR and PLS that contain suitable descriptors for drug design.

## 2. RESULTS AND DISCUSSION

A QSAR study was performed for a series of iminochromene derivatives, for characterizing a quantitative relationship between structure chemical and biological activity. The table 2 shows the values of the calculated parameters calculated with DFT method at B3LYP 6-31G level of the studied molecules. Also, some values of molecular descriptors were obtained by using HyperChem that in table 3 are listed.
Table 2. Values of the descriptors gained at the B3LYP/6-31G level of studied CBR 1 inhibitors

### 2.1. Multiple Linear Regressions (MLR)

The multiple linear regression statistic method is used to study the relation between one dependent variable and several independent variables. Also, minimizes differences between experimental and predicted values. The MLR was acquired using the software SPSS to predict activities $\mathrm{pIC}_{50}$. The Linear Regression method related to a larger family of models called generalized linear models.

The choice of the training set is one of the most significant stages in the QSAR modeling, since the confirmation and optimization of a QSAR model are based on this training set. Applicability and predictability of a QSAR model also relay on the training set selection. The data set $(\mathrm{n}=34)$ was divided casually into two groups: train set $(\mathrm{n}=24)$ and test set $(\mathrm{n}=10)$. The Pearson correlation coefficients are listed in the following table 4. The correlation coefficient $\left(\mathrm{R}^{2}\right)$ matrix for the descriptors used in different MLR equations shows that no significant correlation exists between pairs of descriptors. The acquired matrix gives information on the positive or negative correlation between variables.

Table 4. Correlation coefficient $\left(\mathrm{R}^{2}\right)$ matrix for descriptors represented in multiple linear regression eq. 1.

| Sur $_{\text {Approx }}$ | HE | DM | ZPE | $\mu$ | $\eta$ | Polar |  |

|  |  |  |  |  |  | 1 | Polar |
|  |  |  |  | 1 | 0.611 | 0.154 | $\mu$ |
|  |  |  | 1 | 0.402 | 0.479 | 0.671 | ZPE |
|  |  | -0.261 | -0.548 | -0.094 | 0.133 | DM |  |
|  | 1 | 0.602 | -0.438 | -0.610 | 0.039 | 0.021 | HE |
| 1 | 0.293 | 0.606 | 0.391 | -0.242 | 0.394 | 0.742 | Sur $_{\text {Approx }}$ |

Modeling of $\mathrm{pIC}_{50}$ values of all training iminochromene derivatives take away to the best value corresponding to the linear combination of the descriptors the resulting equation is:
$\mathrm{pIC}_{50}=-9.133-22.630 \times \mu+22.378 \times \eta+0.066 \times$ DM $-8.045 \times$ ZPE $-0.030 \times$ Sur $_{\text {Approx }}+0.536 \times$ Polar $-0.079 \times$ HE $\quad$ (Eq. 1)
We used the $\mathrm{pIC}_{50}$ of the iminochromene derivatives as the dependant variable, equation 1 was resulted from the total of calculated descriptors. This model with acceptable statistical quality ( $\mathrm{R}^{2}=0.836, \mathrm{SE}=0.215$ ) indicated that the inhibitory activity of compounds is influenced by topological parameters (surface area), ZPE, HE and electronic chemical potential values as representative of quantum chemical descriptors. The positive relation of activity and "dipole moment, hardness, polarizibility" displays that increasing of these descriptors cases increasing inhibitory activity of compounds. The obtained descriptors demonstrating the electronic characteristic of the studied molecules listed on table 5. $\mathrm{pIC}_{50}$ predicted of iminochromene derivatives by this model is partly like that observed. Values of $\mathrm{pIC}_{50}$ predicted in table 6 are listed. Also, Fig. 1 displays a very orderly distribution of $\mathrm{pIC}_{50}$ values based on the observed values. The leave-one-out (LOO) approach was applied to carry out the cross-validated analysis. $Q^{2}$ (cross-validated coefficient) is computed using the following equation [22-23]:
$Q^{2}=1-\frac{\sum\left(y_{i}-y_{\text {ipred }}\right)^{2}}{\sum\left(y_{i}-y_{\text {imean }}\right)^{2}}$
Where $y_{i}$ is the $i_{\text {th }}$ experimental $\mathrm{pIC}_{50}$ value, $y_{\text {ipred }}$ is the $i_{\text {th }}$ predicted $\mathrm{pIC}_{50}$ and $\mathrm{y}_{\text {mean }}$ is the mean of the experimental $\mathrm{pIC}_{50}$. The accuracy of the model was mostly estimated by Root Mean Square Error (RMSE) that calculated using the following equation:

RMSE $=\sqrt{\frac{y_{i}-y_{\text {ipred }}}{n}}$
Where $\mathrm{n}=$ number of compounds, $y_{\mathrm{i}}=$ experimental value, $\mathrm{y}_{\mathrm{ipred}}=$ predicted value [24,25]. The RMSE and $\mathrm{Q}^{2}$ of the calibration using MLR method were obtained as 0.207 and 0.835 , respectively. For suitable anticipation model the RMSE values should be low $<0.3$ and $\mathrm{Q}^{2}$ is used as a criterion of both validity and predictive ability of the model.

Table 5. The statistical parameters of different created QSAR models.

[^1]To assess the predictive ability, predictions for all the test objects should be assessed independently of test set composition which can be random or dependent upon the size and distribution of the new data. Validation of models by means of objects whose data have not taken part in the process of model expansion is generally introduced to as external validation. Two different phrases for calculation of external validation $Q^{2}$, that is, $Q 2$ based on predictions for external test compounds, were evaluated [26,27]. These expressions are:
$\mathrm{Q}_{\mathrm{F} 1}^{2}=1-\frac{\sum_{\mathrm{i}=1}^{\mathrm{n}_{\mathrm{EXT}}}\left(\mathrm{y}_{\mathrm{i}}-\hat{y}_{\mathrm{i}}\right)^{2}}{\sum_{\mathrm{i}=1}^{\mathrm{n} E T}\left(\mathrm{y}_{\mathrm{i}}-\bar{y}_{\mathrm{TR}}\right)^{2}}$
$\mathrm{Q}_{\mathrm{F} 2}^{2}=1-\frac{\sum_{\mathrm{i}=1}^{\mathrm{n}_{\mathrm{EXT}}}\left(\mathrm{y}_{\mathrm{i}}-\widehat{y}_{\mathrm{i}}\right)^{2}}{\sum_{\mathrm{i}=1}^{\mathrm{n} \mathrm{EXT}}\left(\mathrm{y}_{\mathrm{i}}-\overline{\mathrm{y}}_{\mathrm{EXT}}\right)^{2}}$
Where $\bar{y}_{\text {TR }}$ and $\bar{y}_{\text {EXT }}$ indicate the response means of the training set and the external test set, respectively. Also, the external predictive ability can be calculated as the following definition [28]:
$\mathrm{Q}_{\mathrm{F} 3}^{2}=1-\frac{\left[\sum_{i=1}^{\mathrm{n}_{\mathrm{EXT}}}\left(\mathrm{y}_{\mathrm{i}}-\widehat{y}_{\mathrm{i}}\right)^{2}\right] / \mathrm{n}_{\mathrm{EXT}}}{\left[\sum_{\mathrm{i}=1}^{\mathrm{n}_{\mathrm{EXT}}}\left(\mathrm{y}_{\mathrm{i}}-\overline{\mathrm{y}}_{\mathrm{TR}}\right)^{2}\right] / \mathrm{n}_{\mathrm{TR}}}$
Values from function $\mathrm{Q}_{\mathrm{F} 1}^{2}, \mathrm{Q}_{\mathrm{F} 2}^{2}$, and $\mathrm{Q}_{\mathrm{F} 3}^{2}, \mathrm{R}^{2}$ values and root-mean-square error over the external evaluation set (RMSE) for eight data sets are listed in Table 7.

Table 7. Model fit estimates(external validation) for iminochromene derivatives data sets.

| Data set | $\mathrm{R}^{2}$ | $\mathrm{Q}_{\mathrm{F} 1}^{2}$ | $\mathrm{Q}_{\mathrm{F} 2}^{2}$ | $\mathrm{Q}_{\mathrm{F} 3}^{2}$ | RMSE |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0.836 | 0.110 | 0.022 | 0.758 | 0.251 |
| 2 | 0.798 | 0.628 | 0.620 | 0.815 | 0.210 |
| 3 | 0.799 | 0.727 | 0.726 | 0.696 | 0.245 |
| 4 | 0.817 | 0.292 | 0.241 | 0.538 | 0.324 |
| 5 | 0.817 | 0.643 | 0.643 | 0.786 | 0.222 |
| 6 | 0.808 | -1.205 | -1.632 | -0.618 | 0.601 |
| 7 | 0.869 | -1.269 | -1.270 | 0.449 | 0.379 |
| 8 | 0.871 | -0.966 | -0.978 | 0.587 | 0.331 |

All the three functions $\mathrm{Q}_{\mathrm{F} 1}^{2}, \mathrm{Q}_{\mathrm{F} 2}^{2}$, and $\mathrm{Q}_{\mathrm{F} 3}^{2}$ in data sets of 2,3 and 5 give suitable approximations of the model fit when test objects are identically distributed and cover the whole range of the training set. Also, 2 data set has the smallest RMSE which corresponds to the largest value of $\mathrm{Q}_{\mathrm{F} 3}^{2}\left(\mathrm{RMSE}=0.210\right.$ and $\left.\mathrm{Q}_{\mathrm{F} 3}^{2}=0.815\right)$.

### 2.2. Partial Least Square analysis (PLS)

PLS technique is a generalization of regression, which can apply data with forcefully correlated and / or numerous independent variables. The linear PLS model detects new variables that are linear combination of the principal variables. To eschewing over fitting, a formidable test for the significance of each successive PLS component is essential and then pausing when the components are non-significant. The PLS have two purposes: to estimate the matrix $X$ of molecular structure descriptors to the matrix Y of dependent variables and to maximize the relationship between them [29]. We presented the data matrix organized clearly from the descriptors offered by MLR corresponding to the molecules, to the PLS. This method used the coefficients $R$, $R^{2}$, and the SE values to chose the best regression performance.

The obtained parameters explaining the electronic aspect of the investigated molecules listed on Table 5. The resulted predictions of the $\mathrm{pIC}_{50}$ using PLS method in gas phase was given in table 6. $\mathrm{pIC}_{50}$ predicted of iminochromene derivatives by PLS method is little similar to that observed. Figure 1 shows a normal distribution of $\mathrm{pIC}_{50}$ values based on the observed values. The resulted parameters describing the electronic aspect of the studied molecules are: $\mathrm{R}^{2}=0.851$ and $\mathrm{RMSE}=0.155$. Cross-validation is a practical and validity method for testing the significance. PLS is usually used in merging with cross-validation to gain the optimum number of components.

### 2.3. Principal Components Analysis (PCA)

The PCA is a helpful statistical technique for summing up all the information coded in the structures of compounds and very useful for identifying the link between the different variables [30]. The molecules of 8-hydroxy-2-iminochromene derivatives were studied by statistical method based on the PCA. The obtained parameters from PCA analysis of the studied molecules are listed on Table 5. The resulted predictions of the $\mathrm{pIC}_{50}$ using PCA method in gas phase were given in Table 6. Values of $\mathrm{pIC}_{50}$ predicted of iminochromene derivatives by PCA method is almost similar to that observed. Figure1 shows a very adequate distribution of $\mathrm{pIC}_{50}$ values based on the observed values. The obtained parameters defining the electronic aspect of the studied molecules are: $\mathrm{R}^{2}=0.908$ and $\mathrm{RMSE}=0.155$. It corroborates that the PCA results were the best to creating the quantitative structure activity relationship models.

## 3. CONCLUSION

In this work, we have studied the QSAR models to predict the activity of iminochromene derivatives. The study of the MLR, PCR and PLS models show that the PCR method has substantially better predictive capability than the other methods. With considering the error, the prediction of the $\mathrm{pIC}_{50}$ values was quite satisfactory and the performance of the QSAR model to predict $\mathrm{pIC}_{50}$ value was also calculated using the internal cross-validation method. The sanity of the three created models used in this study has good consistency and great predictive power. By defining the molecular descriptors in the regression model, we finalize that the decreased surface area, HE, ZPE and electronic chemical potential as well as the increased magnitude of dipole moment, hardness and polarizibility are reliable for the larger activity of the investigated compounds. Eventually, the accuracy and predictability of the suggested models were demonstrated by evaluating essential statistical indexs such, as $Q^{2}$, R2 and RMSE of different models using different statistical models and descriptors, as shown in Table 5.

Figure 1. Correlation of predicted vs. experimental $\mathrm{pIC}_{50}$

## 4. MATERIALS AND METHODS

The inhibitory activity of 8-hydroxy-2-iminochromene derivatives was used. The chemical structures and biological activity of these compounds are listed in Table 1. The specific CBR activities of these compounds were expressed as the effective concentration, which causes the half maximal inhibitory concentration( $\mathrm{IC}_{50}$ ) and then used for QSAR analysis as dependent variables [11]. A complete geometry optimization was carried out with GAUSSIAN 03 program [31] taking the most general conformations as outset geometries. Density functional theory (DFT) calculations [32] of the structures were performed in B3LYP/6-31G level [33]. The molecular descriptors were obtained using HyperChem and GAUSSIAN Packages. Some of quantum chemical descriptors including dipole moment (DM), lowest unoccupied molecular orbital (LUMO) and highest occupied molecular orbital (HOMO) energies, hardness ( $\eta$ ), softness $(\sigma)$, entropy $(\Delta S)$, enthalpy $(\Delta H)$,
 chemical potential $\left(\mu=1 / 2\left(E_{\text {Номо }}+E_{L U M O}\right)\right.$, global electrophilicity index $\left(\omega=\frac{\mu^{2}}{2 \eta}\right)$ and mass [34]. Some chemical parameters including molecular volume (Vol), molecular surface area (Sur), hydrophobicity (logP), polarizability, refractivity (Ref) and hydration energy (HE) were calculated using Hyperchem software.

For each compound in the training sets, the correlation equation was obtained with the same descriptors. Then, the obtained equation was used to predict $\mathrm{pIC}_{50}$ values for the compounds from the corresponding test sets. Totally, 22 descriptors were created. Two programs including SPSS and Minitab were used for MLR, PCA and PLS.
